

Week 3 (Phase 2) - Master Quantitative P&L Report

Data Source: ReportHistory-474167713.html (MT5 Live Execution Data) **System Monitored:** V1 Legacy Runner (unified_runner.py)

1. Executive Summary: The True Cost of Raw Data

By analyzing the true MT5 Closed Trade History (as opposed to live logs), we have a completely accurate picture of our mathematical edge. Because we deliberately turned off the Order Router and Knowledge Register blocking filters to collect raw data, we absorbed the full impact of market noise.

The Bottom Line: - **SuperTrend is the absolute MVP.** It proved its mathematical edge and generated **+\$119.26** in pure profit across 73 trades. - **Ghost Grid is structurally bleeding.** Despite BE_LOCK firing successfully, the widened 0.35xATR SL is resulting in an excessive loss rate (**-\$288.70** combined). - **CAB is struggling with False-Cuts.** CAB generated a **-\$17.46** loss across 139 trades.

2. Individual Bot Performance & P&L

* SuperTrend Bot v2.2 (The Star Performer)

- **Total Trades:** 73
- **Wins / Losses:** 30 Wins (41.1% Win Rate) | 43 Losses
- **Net Profit:** **+\$119.26**
- **Analysis:** SuperTrend is thriving! Despite a 41% win rate, its K-Means factor selection and strict R-Lock trailing logic allow the winners to vastly outperform the losers. It is mathematically carrying the entire portfolio.

* Ghost Grid V1 (The Heavy Bleeder)

(Note: 201 was disabled mid-week for shadow logging) - **Magic 202 (Reversal):** 316 Trades | 125 Wins (39.5%) | **-\$250.10 Profit** - **Magic 201 (Scalp):** 30 Trades | 8 Wins (26.6%) | **-\$38.60 Profit** - **Analysis:** Ghost Grid is failing mathematically. Last week we widened the Stop Loss from 0.20xATR to 0.35xATR to prevent premature stop-outs. While it allowed 128 trades to reach BE_LOCK, the trades that *did* hit the wider SL are causing massive damage.

* CAB Watcher (H4 Inversions)

- **Total Trades:** 139
 - **Wins / Losses:** 42 Wins (30.2% Win Rate) | 97 Losses
 - **Net Profit:** **-\$17.46**
 - **Analysis:** CAB is suffering from severe "False-Cuts". The entry logic is identifying H4 inversions, but the market chops around before committing, triggering the SL prematurely. A 30% win rate requires a massive Reward-to-Risk ratio that CAB is not currently achieving.
-

3. The 10016 Broker Rejection (Naked Trade) Issue

Our 15-second "Kill Switch" inside `sniper_watcher.py` successfully murdered the naked trades this week with a 0.0% failure rate, preventing liquidation.

However, Ghost Grid's massive **-\$288.70 loss** proves that the underlying "Two-Phase" entry architecture is mathematically flawed. We cannot afford to have trades execute at market, fail the SL modification, and get killed 15 seconds later for a random loss.

4. Open Questions for Next Week's Plan

1. **Ghost Grid Stop Loss (Critical):** The wider $0.35 \times \text{ATR}$ SL cost us \$288. Do we revert to $0.20 \times \text{ATR}$ and accept premature stops, or do we dramatically alter the entry logic?
2. **SuperTrend Scale Up:** SuperTrend is our only confirmed winning model (+\$119). Do we increase its risk allocation in `config.json` for next week?
3. **CAB REAPER/SL Settings:** CAB is losing to false-cuts. Do we widen its M15 ATR buffer to let trades breathe, or tighten the REAPER_SI_MAX to cut them even faster?
4. **Architectural Cure for 10016:** Are we ready to implement **Option 1 (Single-Phase Entry)** where we bundle the SL directly into the initial entry ticket to permanently cure the broker rejection bug?
